Python Cheatsheet

Essential syntax, structures, and patterns for modern Python development

This cheatsheet provides a quick reference to fundamental Python concepts, syntax, and advanced features, ideal for both beginners and experienced developers.

Core Syntax
Operators, data types, variables

Functions & Control
Definitions, parameters, flow control

Data Structures
Lists, dicts, sets, tuples

Advanced Patterns
OOP, decorators, comprehensions

File & Package Management
I/O operations, virtual environments

Basics: Operators & Data Types

Operator Precedence

Operators determine how values are combined. Precedence dictates the order of operations.

```
** > % // / * > - +

2 + 3 * 6  # 20 (multiplication before addition)
(2 + 3) * 6  # 30 (parentheses override precedence)
2 ** 8  # 256 (exponentiation)
```

Core Data Types

Python's fundamental data types define the kind of values variables can hold.

```
age = 25  # int (integer, whole number)
price = 19.99  # float (floating-point number, decimal)
name = "Alice"  # str (string, sequence of characters)
is_student = True  # bool (boolean, True or False)
scores = [85, 92, 78]  # list (ordered, mutable collection)
person = {'name': 'Bob'}  # dict (dictionary, key-value pairs)
```

Functions: Definition & Lambda

Functions allow you to encapsulate reusable blocks of code.

```
# Define a function to print a greeting
def say_hello(name):
    print(f'Hello {name}')

say_hello('Carlos')  # Call the function with an argument

# Functions can return values
def sum_two_numbers(a, b):
    return a + b # Returns the sum

# Lambda functions are small, anonymous functions for simple expressions.
add = lambda x, y: x + y # Defines a lambda function that takes x, y and returns their sum
add(5, 3)  # 8
```

Lists & Tuples

Lists (Mutable)

Lists are ordered collections of items that can be changed after creation.

```
furniture = ['table', 'chair']
furniture[0]  # 'table' (access item by index)
furniture[1:3]  # slice (get a sub-list)
furniture.append('bed') # Add item to end
furniture.remove('chair') # Remove specific item
furniture.sort() # Sort items in place
```

Tuples (Immutable)

Tuples are ordered collections similar to lists, but they cannot be changed after creation.

```
coords = (10, 20)
coords[0]  # 10 (access item by index)

# Cannot modify once created
# coords[0] = 15  # Error! (attempting to change an immutable tuple)
```

Dictionaries: Key-Value Pairs

Dictionaries store data in unordered key-value pairs, allowing efficient lookup by key.

```
my_cat = {
    'size': 'fat',
    'color': 'gray',
    'disposition': 'loud'
}

# Add a new key-value pair or modify an existing one
my_cat['age_years'] = 2

# Iterate over key-value pairs in the dictionary
for key, value in my_cat.items():
    print(f'{key}: {value}')

# Safe retrieval: Use .get() to avoid KeyError if the key doesn't exist, providing a default value instead.
my_cat.get('breed', 'unknown')
```

Sets: Unique Collections

Sets are unordered collections of unique items, useful for membership testing and eliminating duplicates.

Create Sets

Sets can be created from a list or by directly listing elements.

```
s = {1, 2, 3} # Directly create a set
s = set([1, 2, 3]) # Convert a list to a set
```

Set Operations

Perform mathematical set operations like union, intersection, and difference.

```
s1 = {1, 2, 3}
s2 = {3, 4, 5}

s1.union(s2)  # {1,2,3,4,5} (all unique elements from both sets)
s1.intersection(s2)  # {3} (elements common to both sets)
s1.difference(s2)  # {1,2} (elements in s1 but not in s2)
```

Control Flow

Control flow statements determine the order in which code instructions are executed.

1

Conditionals

Use `if`, `elif` (else if), and `else` for decision-making logic.

```
if name == 'Debora':
    print('Hi!') # Executes if name is 'Debora'
elif name == 'George':
    print('Hello!') # Executes if name is 'George'
else:
    print('Who?') # Executes if neither of the above conditions are met
```

2

For Loops

Iterate over a sequence (like a list, tuple, or string) or other iterable objects.

```
pets = ['Bella', 'Milo']
for pet in pets: # Loop through each item in the 'pets' list
    print(pet)
```

3

While Loops

Repeats a block of code as long as a specified condition is true.

```
count = 0
while count < 5: # Loop continues while count is less than 5
    print('Hello')
    count += 1 # Increment count to eventually stop the loop
```

Comprehensions: Elegant Iteration

Comprehensions offer a concise way to create lists, sets, or dictionaries based on existing iterables.

```
# List comprehension: Creates a new list from an existing one, optionally with filtering.
names = ['Charles', 'Susan', 'Patrick']
new_list = [n for n in names if n.startswith('C')] # Creates ['Charles']

# Set comprehension: Creates a new set, ensuring unique elements.
{s.upper() for s in {"abc", "def"}}  # {"ABC", "DEF"} (converts strings to uppercase)

# Dictionary comprehension: Creates a new dictionary from an iterable, often transforming key-value pairs.
c = {'name': 'Pooka', 'age': 5}
{v: k for k, v in c.items()}  # Swaps keys and values: {'Pooka': 'name', 5: 'age'}
```

String Formatting: Modern Approach

F-Strings (Python 3.6+)

F-strings (formatted string literals) provide a readable and efficient way to embed expressions inside string literals.

```
name = 'Elizabeth'
f'Hello {name}!' # Embeds variable directly

a = 5
b = 10
f'Sum is {a + b}' # Embeds an expression
```

Format Numbers

F-strings also allow for flexible number formatting.

```
amount = 10000000
f"{amount:,}"  # '10,000,000' (add comma thousands separator)

pi = 3.1415926
f"{pi:.2f}"  # '3.14' (format to two decimal places)
```

String Manipulation

Python offers various methods to work with and modify strings.

```
# Slicing: Extracts parts of a string using start, end, and step indices.
spam = 'Hello world!'
spam[0:5]  # 'Hello' (characters from index 0 up to (but not including) 5)
spam[::-1]  # '!dlrow olleH' (reverses the string)

# String Methods: Common operations like changing case.
greet = 'Hello world!'
greet.upper()  # 'HELLO WORLD!' (converts to uppercase)
greet.lower()  # 'hello world!' (converts to lowercase)
greet.title()  # 'Hello World!' (capitalizes the first letter of each word)

# Join & Split: Combine or break apart strings based on delimiters.
', '.join(['cats', 'rats'])  # 'cats, rats' (joins elements of a list with a comma and space)
'My name is Simon'.split()  # ['My', 'name', 'is', 'Simon'] (splits string into a list of words)
```

Regular Expressions

Regular expressions (regex) are powerful tools for pattern matching and text parsing.

```
import re

# Compile pattern for better performance if used multiple times
phone_regex = re.compile(r'\d\d\d-\d\d\d-\d\d\d\d')
mo = phone_regex.search('My number is 415-555-4242.') # Search for the pattern in a string
mo.group()  # '415-555-4242' (returns the matched string)

# Groups: Use parentheses in the regex to capture specific parts of the match.
phone_regex = re.compile(r'(\d\d\d)-(\d\d\d-\d\d\d\d)')
mo.group(1)  # '415' (first group)
mo.group(2)  # '555-4242' (second group)

# Find all: Returns a list of all non-overlapping matches.
phone_regex.findall('Cell: 415-555-9999 Work: 212-555-0000') # Returns a list of tuples for grouped matches
```

Exception Handling

Handle runtime errors gracefully to prevent program crashes and provide meaningful feedback.

Try-Except

Use `try`, `except`, and `finally` blocks to catch and manage exceptions.

```
try:
    result = 10 / 0 # This will raise a ZeroDivisionError
except ZeroDivisionError: # Catch specific error type
    print('Cannot divide by 0')
finally: # Always executes, regardless of exception
    print('Cleanup')
```

Custom Exceptions

Define your own exception classes for specific error conditions in your application.

```
class MyException(Exception): # Inherit from base Exception class
    pass

raise MyException('Custom error') # Raise an instance of your custom exception
```

File Operations

Interact with the file system to read from or write to files.

```
# Read file: Open a file for reading and get its content. The 'with' statement ensures the file is closed automatically.
with open('file.txt') as f:
    content = f.read()

# Read line by line: Iterate over each line in a file.
with open('file.txt') as f:
    for line in f:
        print(line, end='') # 'end=' prevents extra newlines

# Write file: Open a file for writing. If the file exists, its content is truncated (deleted).
with open('output.txt', 'w') as f:
    f.write('Hello world!\n')

# Append: Open a file for appending. New content is added to the end of the file.
with open('output.txt', 'a') as f:
    f.write('Additional line')
```

Path Operations

The `pathlib` module offers an object-oriented approach to filesystem paths, making operations cleaner and more robust.

```
from pathlib import Path

# Path joining: Concatenate path components securely, handling separators automatically.
print(Path('usr') / 'bin' / 'spam')

# Current directory: Get the path to the current working directory.
Path.cwd()

# Create directories: Make new directories, optionally creating parent directories if they don't exist.
(Path.cwd() / 'new' / 'folder').mkdir(parents=True)

# Check existence: Verify if a path exists and if it's a file or directory.
Path('file.py').exists()  # True if file exists
Path('file.py').is_file()  # True if it's a file
Path('/').is_dir()  # True if it's a directory
```

Decorators: Enhance Functions

Decorators are a powerful way to modify or enhance functions or methods without changing their source code.

```
import functools # Used to preserve the original function's metadata

def your_decorator(func):
    @functools.wraps(func) # Ensures wrapped function retains its original name, docstring, etc.
    def wrapper(*args, **kwargs): # Wrapper function that will be executed instead of the original
        print("Before function") # Code to execute before the original function
        result = func(*args, **kwargs) # Call the original function
        print("After function") # Code to execute after the original function
        return result
    return wrapper

@your_decorator # Apply the decorator to the 'foo' function
def foo():
    print("Hello World!")

foo() # Calling foo() now runs the wrapper logic around it
# Expected output:
# Before function
# Hello World!
# After function
```

*Args & **Kwargs: Flexible Parameters

Use `*args` and `**kwargs` to allow functions to accept an arbitrary number of positional and keyword arguments, respectively.

```
def some_function(*args, **kwargs): # *args collects positional arguments into a tuple, **kwargs collects keyword arguments into a dictionary
    print(f'Arguments: {args}')
    print(f'Keywords: {kwargs}')

some_function('arg1', 'arg2', key1='val1', key2='val2')

# Expected output:
# Arguments: ('arg1', 'arg2')
# Keywords: {'key1': 'val1', 'key2': 'val2'}
```

OOP: Core Concepts

Object-Oriented Programming (OOP) structures code using objects that contain data and methods. Key concepts include:

01

Encapsulation

Bundling data (attributes) and methods that operate on the data within a single unit (class). It restricts direct access to some of an object's components.

```
class MyClass:
    def __init__(self):
        self._protected = 10 # Convention for protected member
        self.__private = 20 # Name mangling for private member
```

02

Inheritance

Allows a class (child/subclass) to inherit attributes and methods from another class (parent/superclass), promoting code reusability.

```
class Animal: # Parent class
    def speak(self): pass # Placeholder method

class Dog(Animal): # Child class inheriting from Animal
    def speak(self): # Overrides parent's speak method
        print("Woof!")
```

03

Polymorphism

Means "many forms." It allows objects of different classes to be treated as objects of a common base class, responding to the same method call in different ways.

```
class Shape: # Base class
    def area(self): pass

class Rectangle(Shape): # Subclass
    def area(self): # Specific implementation of area for Rectangle
        return w * h
```

Dataclasses: Simplified Classes

Dataclasses provide a decorator to automatically generate common methods (`__init__`, `__repr__`, `__eq__`) for classes primarily used to store data.

Basic Dataclass

Define data-holding classes with minimal boilerplate.

```
from dataclasses import dataclass

@dataclass # Decorator to create a dataclass
class Number:
    val: int # Type-hinted field

obj = Number(2)
obj.val  # 2
```

With Defaults

Assign default values to fields directly in the class definition.

```
@dataclass
class Product:
    name: str
    count: int = 0 # Field with default value
    price: float = 0.0 # Another field with default

obj = Product("Python") # 'count' and 'price' use their defaults
obj.count  # 0
```

JSON & YAML

These are common data serialization formats for configuration files and data exchange.

JSON

JavaScript Object Notation (`json` module) is widely used for web data.

```
import json

# Read: Load JSON data from a file into a Python object (dictionary/list).
with open("data.json", "r") as f:
    content = json.load(f)

# Write: Dump Python data (dictionary/list) to a JSON formatted file.
data = {"name": "Joe", "age": 20}
with open("out.json", "w") as f:
    json.dump(data, f, indent=2) # 'indent' makes the output human-readable
```

YAML

YAML Ain't Markup Language (`ruamel.yaml` is a common library) is often used for configuration files due to its human-friendly syntax.

```
from ruamel.yaml import YAML

yaml = YAML() # Initialize YAML parser
with open("config.yaml") as f:
    data = yaml.load(f) # Load YAML data from a file
```

Virtual Environments

Virtual environments isolate Python project dependencies, preventing conflicts between different projects.

virtualenv

A tool to create isolated Python environments.

```
pip install virtualenv # Install virtualenv
mkvirtualenv HelloWorld # Create a new environment
workon HelloWorld # Activate the environment
deactivate # Deactivate the environment
```

Poetry

A dependency management and packaging tool for Python.

```
pip install poetry # Install Poetry
poetry new my-project # Create a new project with a virtual environment
poetry add pendulum # Add a dependency
poetry install # Install dependencies
```

UV (Fast)

A modern, fast Python package installer and resolver.

```
curl -LsSf https://astral.sh/uv/install.sh | sh # Install UV
uv init my-project # Initialize a project with UV
uv add requests # Add a package
uv run python script.py # Run a script within the UV environment
```

Main Entry Point

The `if __name__ == "__main__":` block ensures that certain code only runs when the script is executed directly, not when imported as a module.

```
def add(a, b):
    return a + b

if __name__ == "__main__":
    # This code block will only execute when the script is run directly (e.g., python my_script.py)
    # It will not run if this file is imported into another Python script.
    result = add(3, 5)
    print(result)
```

Built-in Functions: Quick Reference

Python provides a rich set of built-in functions for common tasks.

- **abs()** - Returns the absolute value of a number.
- **all()** - Returns True if all elements in an iterable are true.
- **any()** - Returns True if any element in an iterable is true.
- **enumerate()** - Adds a counter to an iterable, returning it as an enumerate object.
- **filter()** - Constructs an iterator from elements of an iterable for which a function returns true.
- **len()** - Returns the number of items in an object.
- **map()** - Applies a given function to each item of an iterable and returns a map object.
- **max()** / **min()** - Returns the largest/smallest item in an iterable or between two or more arguments.
- **range()** - Generates an immutable sequence of numbers.
- **sorted()** - Returns a new sorted list from the items in an iterable.
- **sum()** - Sums the items of an iterable.
- **zip()** - Combines multiple iterables into a single iterator of tuples.

```
# Examples of built-in functions
len([1, 2, 3])  # 3 (length of the list)
max([1, 5, 3])  # 5 (maximum value in the list)
sorted([3, 1, 2])  # [1, 2, 3] (returns a new sorted list)
list(zip([1, 2], ['a', 'b']))  # [(1, 'a'), (2, 'b')] (combines elements pairwise)
```

Debugging Essentials

Tools and techniques to identify and resolve issues in your code.

Exceptions & Assertions

Exceptions signal errors, while assertions check for conditions that must be true at a certain point in code.

```
# Raise exception: Explicitly trigger an error.
raise Exception('Error message')

# Assertion: Verify a condition. If false, it raises an AssertionError.
status = 'open'
assert status == 'open', 'Must be open' # The message is shown if assertion fails
```

Logging

Logging provides a way to track events that happen when some software runs, offering more flexibility than print statements for debugging and monitoring.

```
import logging

# Configure basic logging to show debug messages
logging.basicConfig(
    level=logging.DEBUG, # Set the logging level (DEBUG, INFO, WARNING, ERROR, CRITICAL)
    format='%(asctime)s - %(levelname)s - %(message)s' # Define output format
)
logging.debug('Program started') # Log a debug message
```

Reference: This cheatsheet covers Python 3.6+ syntax and modern best practices for efficient development.
